The Growth Model: Discrete Time Dynamic Programming

Prof. Lutz Hendricks

Econ720

August 21, 2018

The Issue

We solved the growth model in **sequence language**.

the solution is a sequence of objects that satisfies a bunch of difference equations

An alternative: recursive formulation.

dynamic programming

Dynamic Programming: An Informal Introduction

The basic idea of DP is to transform a many period optimization problem into a static problem.

To do so, we summarize the entire future by a value function.

The value function

- tells us the maximum utility obtainable from tomorrow onwards for any value of the state variables.
- an indirect utility function

Dynamic Programming: An Informal Introduction

Suppose we solve the planner's problem with starting date t^* :

$$\max \sum_{t=t^*}^{\infty} \beta^{t-t^*} u(c_t) \tag{1}$$

subject to $k_{t+1} = f(k_t) - c_t \ \forall t$.

Call the optimal solution c_t^*, k_t^* and the implied lifetime utility V.

Value function

Claim: The only fact that we need to know to figure out V is k_{t^*}

- other past choices do not show up in preferences or constraints
- \triangleright k_{t^*} is the **state variable** of the problem.

Therefore, we can define the **value function** (indirect utility function)

$$V(k_{t^*}) = \sum_{t=t^*}^{\infty} \beta^{t-t^*} u(c_{t^*})$$
 (2)

$$= \max \sum_{t=t^*}^{\infty} \beta^{t-t^*} u(f(k_t) - k_{t+1})$$
 (3)

Time consistency

- ▶ What if we start the problem at $t^* + 1$?
- ▶ Would the planner want to change his optimal choices of k_{t^*+2}, k_{t^*+3} , and so on?
- ► The answer is obviously "no," ... although I won't prove this just yet.
- A problem with this property is known as time consistent:
 - Give the decision maker a choice to change his mind at a later date and he will choose the same actions again.
- Not all optimization problems have this property.
 - ► For example, changing the specification of discounting easily destroys time consistency (self-control problems arise).

Stationarity

- Compare the value functions obtained from the problems starting at t* and at t* + 1.
- ▶ It is obvious that the function $V(k_{t*})$ does not depend on t^* .
- ► That is, solving the problem yields the same value function regardless of the starting date.
- Such a problem is called stationary.
- Not all optimization problems have this property.
 - For example, if the world ended at some finite date, then the problem at t*+1 looks different from the problem at t*.

Recursive structure

Now comes the key insight:

$$V(k_{t^*}) = u(c_t^*) + \beta \left[\sum_{t=t^*+1}^{\infty} \beta^{t-(t^*+1)} u(c_{t^*}) \right]$$
 (4)

$$= u(c_{t^*}) + \beta V(k_{t^*+1})$$
 (5)

$$= \max_{k_{t^*+1}} u(f(k_{t^*}) - k_{t^*+1}) + \beta V(k_{t^*+1})$$
 (6)

We have

- one term reflecting current period utility
- ▶ a second term summarizing everything that happens in the future, given optimal behavior, as a function of k_{t^*+1} .

Recursive structure

Since this equation holds for any arbitrary start date, we may drop date subscripts.

This yields a Bellman equation:

$$V(k) = \max u \left(f(k) - k' \right) + \beta V(k')$$

where the primes denote values in the next period.

Claim: Solving the DP is equivalent to solving the original problem (the Lagrangian).

We will see conditions when this is true later.

Recursive structure

The convenient part of this is: we have transformed a multiperiod optimization problem into a two period (almost static) one.

If we knew the value function, solving this problem would be trivial.

The bad news is that we have transformed an algebraic equation into a **functional equation**.

The solution of the problem is a value function $\emph{\textbf{V}}$ and an optimal policy function

$$c = \phi(k)$$

Note that c cannot depend on anything other than k, in particular not on k's at other dates, because these don't appear in the Bellman equation.

Solution

A solution to the planner's problem is now a pair of functions

$$[V(k), \phi(k)]$$

that solve the Bellman equation in the following sense.

- 1. Given V(k), setting $c = \phi(k)$ solves the max part of the Bellman equation.
- 2. Given that $c = \phi(k)$, the value function solves

$$V(k) = u(\phi(k)) + \beta V(f(k) - \phi(k))$$

Solution: Intuition

Given V(k), setting $c = \phi(k)$ solves the max part of the Bellman equation.

This means:

Point by point, for each k:

$$\phi(k) = \arg\max_{c} u(c) + \beta V(f(k) - c) \tag{7}$$

 $\phi(k)$ simply collects all the optimal c's – one for each k.

Solution: Intuition

$$V(k) = u(\phi(k)) + \beta V(f(k) - \phi(k))$$

Note that this uses the optimal policy function for c.

Think of the Bellman equation as a mapping in a function space:

$$V^{n+1} = T(V^n) = \max u(c) + \beta V^n (f(k) - c)$$

Given an input argument V^n the mapping produces an output arguments V^{n+1} .

The solution to the Bellman equation is the V that satisfies V = T(V).

a fixed point.

The Planner's Problem with DP

The Planner's Bellman equation is

$$V(k) = \max u(c) + \beta V(f(k) - c)$$

with state k and control c.

The FOC for c is

$$u'(c) = \beta \ V'(k')$$

Problem: we do not know V'.

The Planner's Problem with DP

Differentiate the Bellman equation to obtain the envelope condition (aka Benveniste-Scheinkman equation):

$$V'(k) = \beta V'(k')f'(k)$$

Now we can use the FOC to substitute out V' twice:

$$u'(c) = \beta f'(k')u'(c')$$

We obtain the same Euler equation as from the Lagrangian approach.

DP also tells us that the optimal c is a function only of k.

Therefore k' also depends only on k:

$$k' = f(k) - \phi(k)$$
$$= h(k)$$

Capital as control variable

There are other ways of setting up the Bellman equation.

With capital as the control:

$$V(k) = \max_{k'} u(f(k) - k') + \beta V(k')$$

FOC:

$$u'(c) = \beta V'(k')$$

Envelope condition

$$V'(k) = u'(c)f'(k)$$

The general point: We cannot choose the state variables, but we can choose the control variables.

Characterizing the Planner's Solution

It is here where DP has serious advantages over the Lagrangean: one can use results from **functional analyisis** to establish properties of the value function and the policy function.

In our example it can be shown that the economy converges monotonically from any k_0 to the steady state [Sargent (2009), p. 25, fn. 2]:

Note the difference relative to the OLG economy where much stronger assumptions are needed for this result.

Nonstationary Dynamic Programming

What if time matters?

Case 1: Time matters because of an aggregate state variable.

- ► Example: $f(k_t, A_t)$ where $A_{t+1} = G(A_t)$.
- ▶ Solution: Add A_t as a state variable to the value function.

Case 2: Finite horizon problems.

- Example: the household lives until date T.
- ▶ Solution: Add *t* as a state variable to the value function.
- We have one value function per date (see below).

Additional Constraints

Constraints are treated as in any optimization problem.

Example:

 $\max \sum_{t=0}^{\infty} \beta^t u(c_t)$ subject to

- k' = f(k) c
- $k' \ge 0$

Bellman equation:

$$V(k) = \max_{c,k'} u(c) + \beta V(k') + \lambda \left(f(k) - c - k' \right) + \mu k'$$
 (8)

First-order conditions: Kuhn Tucker for k'.

Backward Induction I

For the finite horizon problem: solve it backwards, starting with the last period.

Example:

$$\max \sum_{t=1}^{T} u(c_t) \tag{9}$$

subject to $k_{t+1} = Rk_t - c_t$ and $k_{T+1} \ge 0$.

Bellman:

$$V(k,t) = \max u \left(Rk - k' \right) + \beta V \left(k', t+1 \right) \tag{10}$$

Consider the last date t = T.

- ▶ cannot save: $k_{T+1} = 0$
- ▶ no continuation value: V(k, T+1) = 0
- ▶ the problem is static: just eat all income

Backward Induction II

terminal value:

$$V(k,T) = u(Rk) \tag{11}$$

Now step back to t = T - 1

$$V(k, T-1) = \max u \left(Rk - k'\right) + \beta \underbrace{u \left(Rk'\right)}_{V(k', T)}$$
(12)

• we can (in principle) solve for V(k, T-1)

Now step back to t = T - 2, etc.

Backward Induction

This is mainly useful for numerically solving the problem. Sometimes, one can solve finite horizon problems analytically (see Huggett et al. (2006) for an example).

Example: Non-separable Utility

Example: Non-separable Utility

Consider the following growth economy, modified to include **habit persistence** in consumption.

The social planner solves

$$\max \sum_{t=0}^{\infty} \beta^t u(c_t, c_{t-1})$$

subject to the feasibility constraints

$$k_{t+1} + c_t = f(k_t) + (1 - \delta)k_t$$
 (13)

f satisfies Inada conditions.

Compute and interpret the first-order necessary conditions for the planner's problem.

Sequential Solution

This problem does not fit the DP approach without some modification.

We first solve it using a Lagrangian:

$$\Gamma = \sum_{t=1}^{\infty} \beta^{t} u(f(k_{t}) - x_{t}, f(k_{t-1}) - x_{t-1}) + \sum_{t=1}^{\infty} \lambda_{t} (x_{t} + (1 - \delta)k_{t} - k_{t+1})$$

First order conditions:

$$\beta^{t} u_{1}(t, t-1) + \beta^{t+1} u_{2}(t+1, t) = \lambda_{t}$$

$$f'(k_{t}) \left(\beta^{t} u_{1}(t, t-1) + \beta^{t+1} u_{2}(t+1, t)\right) = \lambda_{t} (1-\delta) - \lambda_{t-1}$$
(14)

Sequential Solution

Euler equation:

$$\lambda_{t-1} = \lambda_t \left[1 - \delta + f'(k_t) \right]$$

Define the total marginal utility of consumption as

$$U'(c_{t-1}) = \beta^{t-1}u_1(t-1,t-2) + \beta^t u_2(t,t-1)$$

The Euler Equation then becomes:

$$U'(c_{t-1}) = U'(c_t) \left(f'(k_t) + 1 - \delta \right)$$
 (15)

Interpretation

$$U'(c_{t-1}) = U'(c_t) \left(f'(k_t) + 1 - \delta \right)$$
 (16)

- ▶ Give up one unit of c_{t-1} . This costs $U'(c_{t-1})$.
- ▶ We can increase x_{t-1} by 1 and raise k_t by 1.
- ▶ We eat the results next period at marginal utility $U'(c_t)$.
- We can eat
 - the additional output $f'(k_t)$;
 - the undepreciated capital 1δ ;

Sequential Solution

A solution of the hh problem is:

Sequences $\{x_t, k_t\}$ that satisfy

- 1. the EE
- 2. the flow budget constraint.
- 3. The boundary conditions k_1 given and a TVC:

$$\lim_{t\to\infty} U'(c_t)k_t=0$$

DP Solution

For DP to work, it must be possible to write the problem as

$$V(s) = \max \ u(s,c) + \beta \ V(s')$$

where s is the state and c is the control.

The current problem does not fit that pattern:

$$V(k) = \max \ u(c, c_{-1}) + \beta \ V(k')$$

subject to the law of motion

$$k' = f(k) + (1 - \delta)k - c$$

$$x = f(k) - c$$

Nonseparable utility is the problem.

Adding a State Variable

The solution is to define an additional state variable

$$z = c_{-1}$$

Then the Bellman equation is

$$V(k,z) = \max_{x} u(f(k) - x, z) + \beta V(x + (1 - \delta)k, f(k) - x)$$

FOC

$$u_1(c,z) = \beta V_k(k',z') - \beta V_z(k',z')$$

Adding a state variable

The envelope conditions are

$$V_{z} = u_{2}(c,z)$$

$$V_{k} = u_{1}(c,z)f'(k) + \beta V_{k}(.')(1-\delta) + \beta V_{z}(.')f'(k)$$

Now define

$$U'(c) = u_1(c,z) + \beta u_2(c',z')$$

Then substitute out the V_z terms:

$$U'(c) = \beta V_k(.')$$

$$V_k = U'(c)f'(k) + (1 - \delta)\beta V_k(.')$$

Substitute out the V_k terms and we get the same EE as with the Lagrangean.

Guess and Verify

Guess and Verify

- In very special cases it is possible to solve for the value function in closed form.
- A common case is
 - ▶ log utility, $u(c) = \ln(c)$, and
 - ► Cobb-Douglas technology with full depreciation: $f(k) = Ak^{\theta}$.
- ▶ Then we can use the "guess and verify" method.

Guess and Verify

The general approach is:

- 1. Guess a functional form for V. Stick this into the right-hand-side of the Bellman equation.
- 2. Solve the max problem given the guess for V. The result is on the left hand side a new value function, V^1 .
- 3. If $V = V^1$ the guess was correct.

Guess and Verify: Example

Consider the growth model with log utility and Cobb-Douglas production / full depreciation.

The planner solves:

$$\max \sum_{t=0}^{\infty} \beta^{t} \ln(c_{t})$$
s.t. $k_{t+1} = A k_{t}^{\theta} - c_{t}$

Guess

Guess

$$V(k) = E + F \ln(k)$$

This is inspired by the hope that V should inherit the form of u. Having capital stock k amounts to having output Ak^{θ} , which would suggest

$$V(k) \cong \ln(Ak^{\theta})$$

= $\ln(A) + \theta \ln(k)$

Note that the guess for V contains some unknown constants (E,F) which we determine as we go along.

First-order Conditions

FOC:

$$u'(c) = \beta V'(k')$$

or

$$1/c = \beta F/k' \tag{17}$$

Envelope condition

$$V'(k) = u'(c)f'(k)$$

or

$$F/k = f'(k)/c \tag{18}$$

Policy Function

We can use the FOC to obtain the policy function in terms of the unknown parameters.

$$Fc = k'/\beta = f'(k)k \tag{19}$$

Note that

$$f'(k)k = \theta f(k) \tag{20}$$

Here, we are lucky and the F drops out

$$k' = h(k) = \beta \,\theta f(k) \tag{21}$$

$$c = (1 - \beta \theta) f(k) \tag{22}$$

Result (as expected): the saving rate is constant.

Recover E and F

Now we need to recover \underline{E} and \underline{F} (and make sure they are indeed constants)

Substitute everything we know into the Bellman equation:

$$E + F \ln(k) = \ln((1 - \beta \theta)f(k)) + \beta \left\{ E + F \ln(\beta \theta f(k)) \right\}$$
 (23)

Note that $\ln(f(k)) = \ln(A) + \theta \ln(k)$.

Collect all the terms that involve k to solve for F

$$F\ln(k) = \theta \ln(k) + \beta F \theta \ln(k)$$
 (24)

implies

$$F = \frac{\theta}{1 - \theta\beta} \tag{25}$$

Collect all the constant terms to solve for E

$$E = \ln(1 - \theta\beta) + \ln(A) + \beta E + \beta F \ln(\theta\beta) + \beta FA$$
 (26)

Summary: Guess and Verify

- 1. Guess a value function (including unknown parameters).
- 2. Write first-order and Envelope conditions using the guess.
- 3. Solve for policy function.
- 4. Substitute policy function into Bellman equation to recover unknown parameters (and check the guess).

Applications

Examples where guess + verify is used:
Huggett et al. (2006), Huggett et al. (2011), Manuelli and Seshadri (2014)
(all models of human capital accumulation)

DP vs Lagrangian

What does DP buy us compared with a Lagrangian?

- With uncertainty, DP tends to be more convenient than a Lagrangian.
- Results from functional analysis can often be used to find properties of the optimal policy function such as monotonicity, continuity, and existence.
- ▶ DP can have **computational** advantages. There are methods for numerically approximating policy functions.
